# UNIT 6

- 6.1 Zinc is highly reactive metal, it may not be possible to replace it from a solution of  $ZnSO_4$  so easily.
- 6.2 It prevents one of the components from forming the froth by complexation.
- **6.3** The Gibbs energies of formation of most sulphides are greater than that for  $CS_2$ . In fact,  $CS_2$  is an endothermic compound. Hence it is common practice to roast sulphide ores to corresponding oxides prior to reduction.
- 6.5 CO
- **6.6** Selenium, tellurium, silver, gold are the metals present in anode mud. This is because these are less reactive than copper.
- **6.9** Silica removes  $Fe_2O_3$  remaining in the matte by forming silicate,  $FeSiO_3$ .
- **6.15** Cast iron is made from pig iron by melting pig iron with scrap iron and coke. It has slightly lower carbon content (» 3%) than pig iron (» 4% C)
- **6.17** To remove basic impurities, like  $Fe_2O_3$
- 6.18 To lower the melting point of the mixture.
- 6.20 The reduction may require very high temperature if CO is used as a reducing agent in this case.

**6.21** Yes, 
$$2Al + \frac{3}{2}O_2 \rightarrow Al_2O_3 \quad \Delta_r G^{\ominus} = -827 \text{ kJ mol}^{-1}$$

$$2Cr + \frac{3}{2}O_2 \rightarrow Cr_2O_3 \quad \Delta_r G^{\ominus} = -540 \text{ kJ mol}^{-1}$$

Hence 
$$Cr_2O_3 + 2Al \rightarrow Al_2O_3 + 2Cr - 827 - (-540) = -287 \text{ kJ mol}^{-1}$$

- 6.22 Carbon is better reducing agent.
- **6.25** Graphite rods act as anode and get burnt away as CO and  $CO_2$  during the process of electrolysis.
- 6.28 Above 1600K Al can reduce MgO.

7.10	Because of inability of nitrogen to expand its covalency beyond 4.											
7.20	Freons	Freons										
7.22	It disse	It dissolves in rain water and produces acid rain.										
7.23	Due to	Due to strong tendency to accept electrons, halogens act as strong oxidising agent.										
7.24	Due to	Due to high electronegativity and small size, it cannot act as central atom in higher oxoacids.										
7.25	Nitrogen has smaller size than chlorine. Smaller size favours hydrogen bonding.

#### UNIT 8

- It is because  $Mn^{2+}$  has  $3d^5$  configuration which has extra stability. 8.2
- 8.5 Stable oxidation states.

 $3d^{3}$  (Vanadium): (+2), +3, +4, and +5

3d<sup>5</sup> (Chromium): +3, +4, +6

3d<sup>5</sup> (Manganese): +2, +4, +6, +7

 $3d^{8}$  (Nickel): +2, +3 (in complexes)

 $3d^4$ There is no  $d^4$  configuration in the ground state.

Vanadate  $VO_3^-$ , chromate  $CrO_4^{2-}$ , permanganate  $MnO_4^-$ 8.6

+3 is the common oxidation state of the lanthanoids 8.10

In addition to +3, oxidation states +2 and +4 are also exhibited by some of the lanthanoids.

- 8.13 In transition elements the oxidation states vary from +1 to any highest oxidation state by one For example, for manganese it may vary as +2, +3, +4, +5, +6, +7. In the nontransition elements the variation is selective, always differing by 2, e.g. +2, +4, or +3, +5 or +4, +6 etc.
- 8.18 Except  $Sc^{3+}$ , all others will be coloured in aqueous solution because of incompletely filled 3*d*-orbitals, will give rise to *d*-*d* transitions.
- (i)  $Cr^{2+}$  is reducing as it involves change from  $d^4$  to  $d^3$ , the latter is more stable configuration 8.21  $(t_{2\sigma}^3)$  Mn(III) to Mn(II) is from  $3d^4$  to  $3d^5$  again  $3d^5$  is an extra stable configuration.

- (ii) Due to CFSE, which more than compensates the 3<sup>rd</sup> IE.
- (iii) The hydration or lattice energy more than compensates the ionisation enthalpy involved in removing electron from  $d^1$ .
- 8.23 Copper, because with +1 oxidation state an extra stable configuration,  $3d^{10}$  results.
- 8.24 Unpaired electrons  $Mn^{3+} = 4$ ,  $Cr^{3+} = 3$ ,  $V^{3+} = 2$ ,  $Ti^{3+} = 1$ . Most stable  $Cr^{3+}$
- 8.28 Second part 59, 95, 102.
- Lawrencium, 103, +3 8.30
