#### Solution:

#### **Formulae** :

 $\bullet \frac{d}{dx} (\sin x) = \cos x$ 

$$\cdot \frac{d}{dx}(kx) = k$$

Let,

$$\frac{d}{dx} \{ 2x \tan^{-1} x - \log(1 + x^2) \} = 2 \tan^{-1} x$$

<u>Formulae</u> :

i) 
$$\frac{d}{dx} (u.v) = u \frac{dv}{dx} + v \frac{du}{dx}$$
  
ii)  $\frac{d}{dx} (tan^{-1}x) = \frac{1}{1+x^2}$   
iii)  $\frac{d}{dx} (kx) = k$   
iv)  $\frac{d}{dx} (kx) = k$   
iv)  $\frac{d}{dx} (u+v) = \frac{du}{dx} + \frac{dv}{dx}$   
v)  $\frac{d}{dx} (x^n) = n \cdot x^{n-1}$   
vi)  $\frac{d}{dx} (u-v) = \frac{du}{dx} - \frac{dv}{dx}$   
Answer :  
Let,  
 $y = 2x \tan^{-1}x - \log(1+x^2)$   
Let  $s = 2x \tan^{-1}x \& t = \log(1+x^2)$   
Therefore,  $y = s - t \dots eq(1)$   
I. For  $2x \tan^{-1}x$   
let  $u = 2x \& v = \tan^{-1}x$ 

therefore,  $\mathbf{s} = \mathbf{u} . \mathbf{v}$ 

Differentiating above equation w.r.t. x,

$$\therefore \frac{ds}{dx} = u \frac{dv}{dx} + v \frac{du}{dx} \dots \left( \because \frac{d}{dx} (u.v) = u \frac{dv}{dx} + v \frac{du}{dx} \right)$$
$$\therefore \frac{ds}{dx} = 2x \frac{d}{dx} (\tan^{-1}x) + \tan^{-1}x \frac{d}{dx} (2x)$$
$$= 2x \cdot \frac{1}{1+x^2} + \tan^{-1}x \cdot 2$$
$$\dots \left( \because \frac{d}{dx} (\tan^{-1}x) = \frac{1}{1+x^2} \& \frac{d}{dx} (kx) = k \right)$$
$$= \frac{2x}{1+x^2} + 2 \tan^{-1}x$$
$$\therefore \frac{ds}{dx} = \frac{2x}{1+x^2} + 2 \tan^{-1}x \dots eq(2)$$

II. For  $log(1 + x^2)$ 

 $let u = (1 + x^2)$ 

therefore,  $t = \log u$ 

Differentiating above equation w.r.t. x,

Differentiating eq(1) w.r.t. x,

$$\therefore \frac{dy}{dx} = \frac{d}{dx}(s-t)$$

$$= \frac{ds}{dx} - \frac{dt}{dx} \dots \left(\because \frac{d}{dx}(u-v) = \frac{du}{dx} - \frac{dv}{dx}\right)$$

$$= \frac{2x}{1+x^2} + 2 \tan^{-1}x - \frac{2x}{1+x^2} \dots \text{from eq(2) and eq(3)}$$

$$= 2 \tan^{-1}x$$

$$\therefore \frac{dy}{dx} = 2 \tan^{-1}x$$

Hence proved !!!

The formula used: (i)  $\cos \theta = \sin \left(\frac{\pi}{2} - \theta\right)$ 

(ii) 
$$\frac{d(\sin^{-1}x)}{dx} = \frac{1}{\sqrt{1-x^2}}$$

We have,  $\sin^{-1}(1 - 2x^2)$ 

- $\Rightarrow$  Putting x = sin $\theta$
- $\theta = \sin^{-1}x \dots (i)$

Putting  $x=sin\theta$  in the equation

⇒ 
$$\sin^{-1}(1 - 2(\sin\theta)^2)$$
  
⇒  $\sin^{-1}(1 - 2\sin^2\theta)$   
⇒  $\sin^{-1}(\cos 2\theta)$   
⇒  $\sin^{-1}(\sin(\frac{\pi}{2} - 2\theta))$ 

$$\Rightarrow \frac{\pi}{2} - 2\theta$$

Now, we can see that  $\sin^{-1}(1 - 2x^2) = \frac{\pi}{2} - 2\theta$ 

Now Differentiating

$$\Rightarrow \frac{d\left(\frac{n}{2} - 2\theta\right)}{dx} = \frac{d\left(\frac{n}{2}\right)}{dx} - \frac{d2\theta}{dx}$$
$$\Rightarrow 0 - \frac{d2\theta}{dx}$$
$$\Rightarrow -2 \frac{d\sin^{-1}x}{dx}$$
$$\Rightarrow \frac{-2}{\sqrt{1 - x^{2}}}$$
Ans)  $\frac{-2}{\sqrt{1 - x^{2}}}$

 $y = \sin^{-1}\left(\frac{2^x \cdot 2}{1+(2^2)^x}\right)$   
 $y = \sin^{-1}\left(\frac{2^x \cdot 2}{1+(2^x)^2}\right)$   
Let  $2^x = \tan\theta$ 

 $\theta = \tan^{-1}(2^x)$ 

Putting  $2^x = \tan \theta$ 

$$y = \sin^{-1} \left( \frac{\tan \theta \cdot 2}{1 + (\tan \theta)^2} \right)$$

$$y = \sin^{-1} \left( \frac{2\tan \theta}{1 + \tan^2 \theta} \right)$$

$$y = \sin^{-1} (\sin 2\theta)$$

$$y = 2\theta$$

$$y = 2\tan^{-1} (2^x)$$
Now Differentiating
$$\Rightarrow \frac{d(2\tan^{-1}(2^x))}{dx}$$

$$\Rightarrow 2\frac{d(\tan^{-1}(2^x))}{d2^x} \frac{d2^x}{dx}$$

$$\Rightarrow 2\frac{1}{1 + (2^x)^2} \cdot 2^x \log 2$$

$$\Rightarrow \frac{2^{1+x} \log 2}{1 + 4^x}$$
Ans)  $\frac{2^{1+x} \log 2}{1 + 4^x}$

### Solution:

Let us differentiate the whole equation w.r.t  $\boldsymbol{x}$ 

Formula :  $\frac{d(x^n)}{dx} = n \times x^{(n-1)}$ 

According to the chain rule of differentiation

$$\frac{d(y^2)}{dx} = \frac{d(y^2)}{dy} \times \frac{dy}{dx} = 2y \times \frac{dy}{dx}$$

Therefore,

$$\frac{d(x^2)}{dx} + \frac{d(y^2)}{dx} = \frac{d(4)}{dx}$$
$$2x + 2y \times \frac{dy}{dx} = 0$$
$$\frac{dy}{dx} = \frac{-2x}{2y}$$

Formula :  $\frac{d(\tan x)}{dx} = \sec^2 x$ 

According to product rule of differentiation

$$\frac{d(xy)}{dx} = \frac{xdy}{dx} + \frac{yd(x)}{dx} = x \times \frac{dy}{dx} + y$$

Therefore,

$$\frac{d(xy)}{dx} = \frac{d(\tan xy)}{dx}$$

$$x\frac{dy}{dx} + y = \sec^2(xy) \times \frac{d(xy)}{dx}$$

$$x\frac{dy}{dx} + y = \sec^2(xy) \times [x\frac{dy}{dx} + y]$$

$$\frac{dy}{dx} [x - x\sec^2(xy)] = y\sec^2(xy) - y$$

$$x\frac{dy}{dx} (1 - \sec^2 xy) = y(\sec^2(xy) - 1)$$

$$\frac{dy}{dx} = \frac{-y(1 - \sec^2(xy))}{x(1 - \sec^2 xy)}$$

$$\frac{dy}{dx} = \frac{-y}{x}$$

### **Question: 22**

Find , when: <

### Solution:

Let us differentiate the whole equation w.r.t  $\boldsymbol{x}$ 

Formula: 
$$\frac{d(x^n)}{dx} = n \times x^{(n-1)}$$
,  $\frac{d(\log x)}{dx} = \frac{1}{x}$ 

According to product rule of differentiation

$$\frac{d(y\log x)}{dx} = \frac{\log x \, d(y)}{dx} + \frac{y \, d(\log x)}{dx} = \log x \times \frac{dy}{dx} + \frac{y}{x}$$

Therefore,

$$\frac{d(y \times \log x)}{dx} = \frac{d(x-y)}{dx}$$
$$\log x \times \frac{d(y)}{dx} + \frac{y}{x} = 1 - \frac{d(y)}{dx}$$
$$\frac{dy}{dx} [\log x + 1] = 1 - \frac{y}{x}$$
$$\frac{dy}{dx} [(1 + \log x)^2] = 1 - \frac{y}{x} (1 + \log x)$$

(Multiply by  $1 + \log x$  on both sides)

$$\frac{dy}{dx}[(1+\log x)^2] = 1 + \log x - \frac{y}{x} - \frac{y}{x}\log x$$
$$\frac{dy}{dx}[(1+\log x)^2] = 1 + \log x - \frac{y}{x} - \frac{(x-y)}{x}(y\log x = x - y)$$
$$\frac{dy}{dx}[(1+\log x)^2] = 1 + \log x - \frac{y}{x} - 1 + \frac{y}{x}$$
$$\frac{dy}{dx} = \frac{\log x}{(1+\log x)^2}$$

Find , when: <

### Solution:

Let us differentiate the whole equation w.r.t  $\boldsymbol{x}$ 

Formula : 
$$\frac{d(\cos x)}{dx} = -\sin x$$

According to chain rule of differentiation

$$\frac{d(\cos y)}{dx} = \frac{d(\cos y)}{dy} \times \frac{dy}{dx} = -\sin y \times \frac{dy}{dx}$$

According to product rule of differentiation

$$\frac{d(x\cos(y+a))}{dx} = x\frac{d(\cos y+a)}{dx} + \cos(y+a)$$

Therefore,

$$\frac{d(\cos y)}{dx} = \frac{d(x\cos(y+a))}{dx}$$
$$-\sin y \frac{dy}{dx} = x \frac{d(\cos(y+a))}{dx} + \cos(y+a)$$
$$-\sin y \frac{dy}{dx} = x(-\sin(y+a)\frac{dy}{dx}) + \cos(y+a)$$
$$\frac{dy}{dx}[-\sin y + x\sin(y+a)] = \cos(y+a)$$
$$\frac{dy}{dx} = \frac{\cos(y+a)}{x\sin(y+a) - \sin y}$$
$$\frac{dy}{dx} = \frac{\cos(y+a)}{x\cos(y+a)\sin(y+a) - \cos(y+a)\sin y}$$

( Multiply and divide by  $\cos(y+a)$  )

$$\frac{dy}{dx} = \frac{\cos^2(y+a)}{\sin(y+a)\cos y - \cos(y+a)\sin y} \text{ (Since } \cos y = x \cos (y + a)\text{)}$$

$$\frac{dy}{dx} = \frac{\cos^2(y+a)}{\sin(y+a-y)} \text{ (Formula } \sin(a-b) = \sin a \cos b - \cos a \sin b\text{)}$$

$$\frac{dy}{dx} = \frac{\cos^2(y+a)}{\sin a}$$

# **Question: 24**

Find , when: <

### Solution:

Let us differentiate the whole equation w.r.t  $\boldsymbol{x}$ 

Formula : 
$$\frac{d(\cos^{-1}x)}{dx} = -\frac{1}{\sqrt{1-x^2}}$$

According to the chain rule of differentiation

$$\frac{d(y^2)}{dx} = \frac{d(y^2)}{dy} \times \frac{dy}{dx} = 2y \times \frac{dy}{dx}$$

Therefore,

$$\frac{d(\cos^{-1}\frac{x^2 - y^2}{x^2 + y^2})}{dx} = \frac{d(\tan^{-1}a)}{dx}$$

$$-\frac{1}{\sqrt{1 - (\frac{x^2 - y^2}{x^2 + y^2})^2}} \times \frac{d(\frac{x^2 - y^2}{x^2 + y^2})}{dx} = 0$$

$$\frac{d(\frac{x^2 - y^2}{x^2 + y^2})}{dx} = 0$$

$$\frac{x^2 + y^2 \left[\frac{d(x^2 - y^2)}{dx}\right] - (x^2 - y^2)[\frac{d(x^2 + y^2)}{dx}]}{(x^2 + y^2)^2} = 0$$

$$x^2 + y^2 \left[\frac{d(x^2 - y^2)}{dx}\right] - (x^2 - y^2)[\frac{d(x^2 + y^2)}{dx}] = 0$$

$$(x^2 + y^2) \left(2x - 2y\frac{dy}{dx}\right) - (x^2 - y^2)(2x + 2y\frac{dy}{dx}) = 0$$

$$(x^2 + y^2) \left(x - y\frac{dy}{dx}\right) = (x^2 - y^2)(x + y\frac{dy}{dx})$$

$$\frac{dy}{dx} \left[-x^2y - y^3 - x^2y + y^3\right] = x^3 - xy^2 - x^3 - xy^2$$

$$\frac{dy}{dx} \left[-2x^2y\right] = -2xy^2$$

$$\frac{dy}{dx} = \frac{-2xy^2}{-2yx^2}$$

### **Question: 15**

Find

#### Solution:

Here, the argument of the sinusoidal function has exponent as x itself.

For that, we will consider  $x^x = u$  for simplicity.

 $y = \sin u$ 

Differentiating both the sides,

$$\frac{dy}{dx} = \cos u \times \frac{du}{dx}.$$
 (1)

Now we have to find  $\frac{du}{dx}$  , where  $u = x^x$ 

take log both the sides

 $\ln u = x \ln x$ 

Now differentiating both sides by x, we get,

$$\frac{1}{u} \times \frac{du}{dx} = x \left(\frac{1}{x}\right) + \ln x$$
$$\frac{du}{dx} = (1 + \ln x) \times u$$

# **Question: 60**

#### Solution:

equality is not given but we may assume that it is equal to 0.

We can also write this equation as

$$y - e^{(x^2-3)\ln x} + e^{x^2\ln(x-3)} = 0$$

Now differentiating it,

$$y' - x^{x^2 - 3} \left( \frac{x^2 - 3}{x} + \ln x \cdot 2x \right) + (x - 3)^{x^2} \cdot \left( \frac{x^2}{x - 3} + \ln(x - 3) \cdot 2x \right) = 0$$
$$y' = x^{x^2 - 3} \left( \frac{x^2 - 3}{x} + \ln x \cdot 2x \right) - (x - 3)^{x^2} \cdot \left( \frac{x^2}{x - 3} + \ln(x - 3) \cdot 2x \right)$$

### **Question: 61**

If <

#### Solution:

take log both the side,

$$\ln f(x) = (2+3x) \cdot \ln\left(\frac{3+x}{1+x}\right)$$

Now differentiate it,

$$\frac{1}{f(x)} \times f'(x) = (2+3x) \left(\frac{1+x}{3+x}\right) \left(\frac{1+x-(3+x)}{(1+x)^2}\right) + \ln\left(\frac{3+x}{1+x}\right).3$$
$$f'(x) = \left(\frac{(2+3x)(-2)}{(3+x)(1+x)} + 3.\ln\left(\frac{3+x}{1+x}\right)\right) \times f(x)$$

To get f'(0) we need to find f(0),

Putting x=0 in f

$$f(0) = \left(\frac{3}{1}\right)^2$$

$$f(0) = 9$$

Now put x=0 in f'(x),

$$f'(0) = \left(\left(\frac{2 \times (-2)}{3}\right) + 3\ln 3\right) \times 9$$
$$f'(0) = 9\left(3\ln 3 - \frac{4}{3}\right)$$

Substituting the above values in  $\tan^{-1}\frac{1-\sin\theta}{\cos\theta}$  , we get

### Solution:

Theorem: y and x are given in a different variable that is  $\theta$ . We can find  $\frac{dy}{dx}$  by finding  $\frac{dy}{d\theta}$  and  $\frac{dx}{d\theta}$  and then dividing them to get the required thing.

$$\frac{dy}{d\theta} = \frac{d(2\sin\theta - \sin2\theta)}{d\theta}$$

$$= 2\cos\theta - 2\cos2\theta \dots \dots \dots (1)$$

$$\frac{dx}{d\theta} = \frac{d(2\cos\theta - \cos2\theta)}{d\theta}$$

$$= -2\sin\theta + 2\sin2\theta \dots \dots (2)$$
Dividing (1) and (2), we get
$$\frac{dy}{dx} = \frac{2\cos\theta - 2\cos2\theta}{2\sin2\theta - 2\sin\theta}$$

By factorising numerator, we get

$$= \frac{(1-\cos\theta)(\cos\theta+\frac{1}{2})}{2\sin\theta(\cos\theta-\frac{1}{2})}$$
$$= \frac{1-\cos\theta}{2\sin\theta} \times \frac{\cos\theta+\frac{1}{2}}{\cos\theta-\frac{1}{2}} \left\{ \frac{1-\cos\theta}{\sin\theta} = \tan\left(\frac{\theta}{2}\right) \right\}$$

Foe simplicity let's take  $\theta/2$  as x.

$$= \frac{tanx}{2} \times \frac{2 - 2 \tan^2 x + 1 + \tan^2 x}{2 - 2 \tan^2 x - 1 - \tan^2 x}$$
$$= \frac{tanx}{2} \times \frac{3 - \tan^2 x}{1 - 3 \tan^2 x}$$

$$= \frac{3tanx - \tan^3 x}{1 - 3\tan^2 x} \frac{3tanx - \tan^3 x}{1 - 3\tan^2 x} = \tan 3x$$
$$= \frac{tan3x}{2} x = \frac{\theta}{2}$$
