T Tips & Tricks

■ Badecker reaction: This reaction involves the following chemical change.

 $Na_2[Fe(CN)_5NO] + Na_2SO_3 \rightarrow Na_4[Fe(CN)_5(NO.SO_3)]$

- **Exeritt's salt :** It is $K_2[Fe(CN)_6]$ obtained by reduction of prussian blue.
- **Masking**: Masking is the process in which a substance without physical separation of it is so transformed that is does not enter into a particular reaction e.g., masking of Cu^{2+} by CN^- ion.
- **Macrocyclic effect:** This term refers to the greater thermodynamic stability of a complex with a cyclic polydentate ligand when compared to the complex formed with a non-cyclic ligand. e.g., Zn(II) complex with ligand;

complex with ligand;

NH NH

is more stable

NH NH

NH H2

- \mathcal{L} In octahedral complexes, the energy of the d_{z^2} and $d_{x^2-y^2}$ orbitals increases much more than the energy of the d_{xy}, d_{yz}, d_{xz} orbitals. The potential energy increases as a result of repulsive interactions. The greater the repulsion, greater is the increases in energy.
- ∠ Ligands with larger groups from unstable rings than the ligands with smaller groups. This is ascribable to steric hinderance produced by a larger group.
- \varnothing When Ca^{2+} or Mg^{2+} forms complexes with EDTA, the pH of the solution decreases.

blue when excess of ammonia is added. This is also due to the formation of $[Cu(NH_3)_4]SO_4$

- \mathcal{L} Co-ordination compound with a general formula MA₄, MA₃B or MABCD do not show any geometric isomerism.
- Æ Flexidentate character: polydentate ligand are said to have flexidentate character if they do not use all its donar atoms to get coordinated to the metal ion e.g., EDTA generally act as a hexadentate ligand but it can also act as a pentadentate and tetradentate ligand.
- \mathcal{E} Octahedral complex of the type [M(ABCDEF)] have 15 different geometrical isomers with a pair of enantiomers. Although a few geometrical isomer have been prepared but none has been resolved e.g., [Pt (Py)(NH_3)(NO_2)(Cl)(Br)I].

Critical Thinking Questions

$$[Co\ (NH_3)_5\ Br_2]SO_4 + BaCl_2 \rightarrow$$

$$[Co(NH_3)_5Br]Cl_2 + BaSO_4$$

On using one lit. solution, we will get 0.01 mole y and 0.01 mole z.

- **4.** (b) $[Fe(\eta^5 C_5H_5)_2]$ is the organometallic compound which has σ and π bonds present.
- 5. (b) $[Ni_{x}(NH_{3})_{4}]SO_{4}$ $x+0+(-2)=0 \Rightarrow x=+2 \text{ is valency and 4 is } C.N.$ of Ni.
- **6.** (b) Co-ordination number is equal to total number of ligands in a complex.

7. (c)
$$n \begin{bmatrix} Cl & Cl \\ Si \\ CH_3 & CH_3 \end{bmatrix} + 2nH_2O \rightarrow \begin{pmatrix} CH_3 \\ -O - Si - O - \\ CH_3 \end{pmatrix}_n$$

- 8. (c) Because it is a polydentate ligand which binds the central atom nickel forming a ring like structure.
- 9. (d) $4KCN + CuSO_4 \rightarrow K_3[Cu(CN)_4]$ Potassium tetracy no cupra

10. (a) Roasted
$$+CN^{-} + H_{2}O \xrightarrow{O_{2}} [Au(CN)_{2}]^{-} + OH^{-}$$
gold ore
$$[Au(CN)_{2}]^{-} + Zn \rightarrow [Zn(CN)_{4}]^{2-}.$$

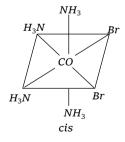

11. (d) Potassium ferrocynide $K_4[Fe(CN)_6]$ will ionize as $K_4[Fe(CN)_6] = 4K^+ + [Fe(CN)_6]^{4^-}$

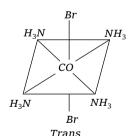

So, it will give five ions in solution.

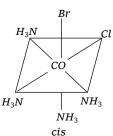

12. (d) Complex ion Hybridization of central atom

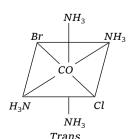

$$[Fe(CN)_6]^{4-}$$

 $[Mn(CN)_6]^{4-}$ d^2sp^3 (inner)
 $[Co(NH_3)_6]^{3+}$ d^2sp^3 (inner)
 $[Ni(NH_3)_6]^{2+}$ sp^3d^2 (outer)

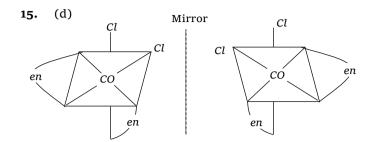

- **13.** (d) $[Co(en)_2 Cl_2]^+$ shows geomerical as well as optical isomerism.
- **14.** (a)

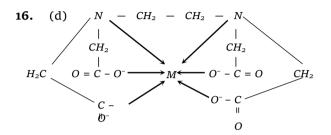

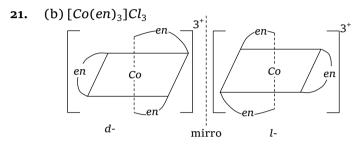

Ethylenediamine tetraacetate ion (EDTA)

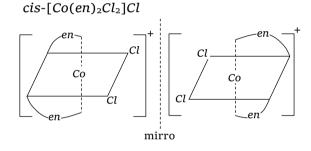

They have six donor atoms. poly dentate ligands have flexidentate character. It is not necessary that all the donor atoms present in the polydentate ligands should form coordinate bonds with central metal atom or ion.

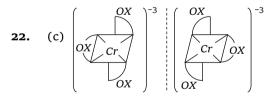

- 17. (a,d) In $K_3[Fe(CN)_6]$ the ligand are negative which is present in coordination spheres shows a dual behaviour. It may satisfied both primary & secondary valencies while neutral ligand satisfied only secondary valencies.
- 18. (a) Cis Isomer of $[Pt(NH_3)_2Cl_2]$ is used as an anticancer drugs for treating several type of malignant tumours. When it is injected into the blood stream the more reactive Cl groups are lost so the Pt atom bonds to a N atom in guanosine (a part of DNA) This molecule can bond to two different guanosine units & by bridging between them it upsets the normal reproduction of DNA.
- 19. (c) $CoCl_2$ is a weak Lewis acid, reacting with chloride ion to produce salt containing the tetrahedral $[CoCl_4]^{2-}$ ion. $CoCl_2$ is blue when anhydrous, and a deep magneta colour when hydrated, for this reason it is widely used as an indicator for water.
- **20.** (a) The absorption of energy or the observation of colour in a complex transition compound depends on the charge of the metal ion and

the nature of the ligands attached. The same metal ion with different ligands shows different absorption depending upon the type of ligand. The presence of weak field ligands make the central metal ion to absorb low energies *i.e.*, of higher wavelength. The field strength of ligands can be obtained from spectrochemical series. *i.e.*

(weak field) $I^- < Br^- < S^{2-} < Cl^- < NO_3^- < F^- < OH^- < H_2O < NH_3 < NO_2^- < CN^- < CO$ (strong field)

Assertion and Reason

- (d) Potassium ferrocyanide and potassium ferricyanide both are not diamagnetic because both do not have paired electrons. Assertion and reason both are false.
- 2. (c) It is correct statement that NF_3 is a weaker ligand than $N(CH_3)_3$, the reason is that fluorine is highly electronegative therefore, it with draw electrons from nitrogen atom. Hence, the lone pair of nitrogen atom cannot be ligated. While $N(CH_3)_3$ is a strong ligand because CH_3 has electron releasing group.

- 3. (d) Both assertion and reason are false. $[Ni(en)_3]Cl_2 \quad \text{is a chelating compound and}$ chelated complexes are more stable than similar complexes involves breaking of two bonds rather than one. In $[Ni(en)_3]Cl_2$, Ni with d^8 configuration shows octahedral geometry. Six electrons will occupy the t_{2g} orbitals and two electrons will occupy the e_g orbitals.
- 4. (a) Both assertion and reason are true and reason is the correct explanation of assertion. When a monodentate ligand has two possible donor atoms and attached in two ways to the central metal atom are called ambidentate ligands.
- 5. (c) Assertion is true but reason is false. Tetrahedral complexes do not show geometrical isomerism because the relative position of the atoms with respect to each other will be the same.
- **6.** (e) Assertion is false but reason is frue.

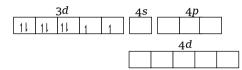

$$\begin{bmatrix} (en)_2 Co \\ OH \end{bmatrix} Co (en)_2$$
 is named as

tetrakis (ethylene diamine)- μ -hydroxo- μ -imido dicobalt (III) ion. For more than one bridging group the word μ is repeated before each bridging group.

7. (b) Both assertion and reason are true but reason is not the correct explanation of assertion. $[Fe(CN)_6]^{3-}$ has EAN equal to 35 and thus possesses unpaired electron to show paramagnetic nature while $[Fe(CN)_6]^{4-}$

- possesses no unpaired electron and thus shows diamagnetic nature.
- **8.** (e) Assertion is false but reason is true. H_2N-NH_2 does not act as chelating ligand. The coordination by hydrazine leads to a three member highly unstable strained ring and thus it does not act as chelating agent.
- **9.** (a) Both assertion and reason are true and reason is the correct explanation of assertion. $[Sc(H_2O)_6]^{3+}$ has no unpaired electron in its d subshell and thus d-d transition is not possible whereas $[Ti(H_2O)_6]^{3+}$ has one unpaired electron in its d subshell which gives rise to d-d transition to impart colour.
- 10. (b) Both assertion and reason are true but reason is not the correct explanation of assertion.

Ni²⁺ configuration

During rearrangement only one 3d-orbital may be made available by pairing the electrons. Thus, inner d^2sp^3 hybridization is not possible, so, only sp^3d^2 (outer) hybridization can occur.

11. (c) $K_4[Fe(CN)_6]$ and $K_3[Fe(CN)_6]$ both are low spin complex due to strong ligand field. That is why it is false that crystal field splitting in ferrocyanide ion is greater than ferricyanide ion.
