Photosynthesis

Historical Background :-

(1) Van Helmont :-

→ Food comes from water not the soil.

(2) Joseph Priestley :-

→ plants restore to the air whatever breathing animals & burning candle removes.

Exp:- plant & candle in closed jar

(3) Jan Ingenhousz :-

→ sunlight is essential for P.S.

→ exp. on aquatic plants.

(4) Sachs :-

→ plants produce glucose during P.S.

(5) Engelmann' :-

→ exp. with green algae 'CLADOPHORA'

→ Carried out Action Spectrum.

(6) Van Niel :-

→ exp. on purple-green bacteria.

→ P.S. is light dependent.

→ H_2 from suitable oxidisable compound is used to reduce CO_2 .

(7) Robert Hill :-

→ Plant use light energy to generate reducing power.

(8) Theodore de Saussure :-

→ H_2O is essential for P.S.

(9) Emerson :-

→ 2 photosystem are there. (PS-I, II).

→ Emerson's effect (Red Drop).

→ Light & Dark reactions.

(10) M. Calvin :-

→ C_3 cycle.

Photosynthesis :-

Raw material :-

H_2O & CO_2 , Sunlight and pigments

Three types of Pigments for Photosynthesis :-

(1) Chlorophyll :-

↓
Ch-a, b, c, d, e, bacterio chlorophyll
bacterio viridin.

(2) Chlorophyll $\left\{ \begin{array}{l} \rightarrow \text{Head} \rightarrow \text{Porphyrin Head} \\ \rightarrow \text{Tail} \rightarrow \text{Phytol side chain} \end{array} \right.$

On the next page,

we will discuss difference b/w

Ch-a & b.

Ch-a

- at position 'R',
-CH₃ group is present
- Bluish Green
- In reflected light
it appears Red.
- In transmitted light
appears Green.

Ch-b

- at position 'R',
-CHO group is present
- Olive Green.
- In reflected light
it appears Brownish
Red.
- In Transmitted light
appears yellowish-green.

* Structure of chlorophyll c-

(2) Carotenoids (lipids) :-

(a) Carotene

→ $C_{40}H_{56}$

→ Orange Red

(b) Xanthophylls

→ $C_{40}H_{56}O_2$

→ Yellowish Brown

Ex:- Fucoxanthin, Lutein

(3) Phycobillins :-

→ Predominant in BGA.

(a) Phycocyanin

→ purple

(b) Phycoerythrin

→ Red

Note:-

Ch-a ← Reaction Center chlorophyll

all other pigments ← Accessory pigments

Site of photosynthesis :-

Leaf → mesophyll cells → Chloroplast.

* Light dependent photosynthesis

↓
Light Rxn ← Grana

* Light Independent photosynthesis

↓
Dark Rxn

C_3 cycle / calvin cycle ← Stroma

Thylakoid
or
Granum

#1 Light absorption & Action Spectrum:-

Light Quality $\Rightarrow$ means wavelength.

$\rightarrow$ Every pigment absorbs different wavelength of light.

$\rightarrow$ most of the absorption takes place by chlorophyll-a & b at 500 and 700 nm

$\rightarrow$ The absorption of light is depicted by a graph called 'ABSORPTION SPECTRUM'.

$\rightarrow$ The absorption spectrum is also referred to as 'ACTION SPECTRUM', because rate of photosynthesis is high at 500 & ~~680~~ 700 nm.

$\rightarrow$ Action Spectrum was discovered by a scientist named Engelmann's by his exp. on green algae.

$\rightarrow$ Action spectrum is recorded by Spectrophotometer

Hence,
Blue and Red light is mostly preferred for photosynthesis.

11 Emerson's effect & Red Drop:-

* Quantum Yield:-

→ amount of O_2 released per quantum of light absorbed.

* Red Drop:-

→ Sudden decline in the rate of Photosynthesis after 680 nm (red.)

When leaf exposed individually to:-

P.S. at 700 nm $\Rightarrow$ 10 qu. yield

P.S. at 683 nm $\Rightarrow$ 53 qu. yield

But,

when leaf exposed simultaneously at 700 & 683,

P.S. at 700 & 683 $\Rightarrow$ (72) qu. yield

↑
Enhanced Q.Y.

* Emerson's Enhancement Effect:-

→ at exposition to 700 & 683 nm of light simultaneously, the Q.Y. is much higher than individually exposed to 700 & 683 nm.

→ There are 2 photosystems.

PS - I
(700 nm)

PS - II
(680 (653-680))

#1 Quantosome :-

→ It is the photosynthetic Unit.

→ It is a collection of pigments molecules which help in photosynthesis.

Fig! → Quantosome

Now,

when an isolated "chlorophyll-a" is taken in test tube, it shows Fluorescence (emission of colour).

#1 Photosystem :-

→ There are two types of photosystem namely PS-I & PS-II.

→ Discovered by Engelman.

Photosynthesis :-

Non-cyclic Photophosphorylation :-

- occurs in Thylakoids.
- Continuous supply of electrons and a pair of proton is provided by photolysis of water.

→ Also called as 'Z Scheme'.

→ Both PS-I, PS-II are involved.

→ End products are ATP, O_2 , $NADPH_2$

→ A pair of e^- is excited in presence of Sunlight & pass through E.T.S. to release ATP.

→ The photolysis of H_2O provides $2H^+$ to $NADP^+$ to form $NADPH_2$

↓
A reducing substance which reduces CO_2 to carbohydrates in Dark rxn.

→ Complex for photolysis of H_2O is present on inner membrane of thylakoid. i.e, O_2 is collected in lumen of thylakoid.

→ NADP reductase ~~enz~~ catalyst is present on outer membrane of thylakoid.

PEA $\rightarrow$ Primary e^- acceptor.

PQ $\rightarrow$ Plasto Quinone

Cy $\rightarrow$ Cytochrome Complex

PC $\rightarrow$ Plastocyanine

Fd $\rightarrow$ Ferredoxine.

Cyclic Photophosphorylation :-

$\rightarrow$ Only PS-I is involved.

$\rightarrow$ No photolysis of H_2O .

$\rightarrow$ Only ATP is synthesized.

$\rightarrow$ No reducing power ($NADPH_2$) is generated.

$\rightarrow$ Occurs in stroma lamellae.

Note:-

During photosynthesis,

only 15-20% process is cyclic
otherwise, maximum process is non-cyclic
(O_2 liberation).

Comparison b/w cyclic & Non-cyclic Photophosphorylation

Characters	Cyclic Photophosphorylation	Non-cyclic Photophosphorylation
1. Product Synthesized	Only ATP	ATP & NADPH ₂
2. Byproduct	× × × × ×	O ₂ is the byproduct
3. O ₂ evolved	× × ×	✓
4. PS. requirement	PS-I	PS-II & PS-I
5. Source of e ⁻	No external source of e ⁻ is needed	H ₂ O is the external source of e ⁻
6. Condition Req.	→ low int. of light → low conc. of CO ₂ → In anaerobic condn.	→ optimum int. of light. → conc. of CO ₂ is high. → In aerobic.

Comparison b/w PS-I & PS-II :-

Characters	PS-I	PS-II
1. Reaction Center	P700 (chl-a)	P680 (chl-a)
2. Cyclic	Involved in both cyclic & non-cyclic photophosphorylation.	Involved only in Non-cyclic photophosphorylation.
3. Ratio of chlorophyll & carotenoids	chl : Carotenoids 20-30 : 1	chl : Carotenoids 3.7 : 1
4. Location	On the membrane of thylakoid & stroma lamellae both.	On membrane of thylakoid only.
5. Oxygen	PS-I is not associated with photolysis complex	PS-II is associated with photolysis complex
6. Source of e ⁻	from chl-a in cyclic P.P. from P-S-II in noncyclic P.P.	From → photolysis of water

ii Chemiosmotic Theory / Hypothesis :-

→ site of H_2O splitting. ~~Is on the complex~~
Inner side of membrane of thylakoid.

→ site of NADP reductase enzyme is
Outer membrane of thylakoid.

→ site of O_2 produced = lumen

→ site of ATP & $NADPH_2$ production is
Stroma.

→ F_0 particle helps in facilitated
diffusion of H^+ .

→ cytochrome acts as H^+ acceptor as
well as e^- transporter.

Fig:- Thylakoid

Dark Reaction / C₃ cycle / Calvin cycle :-

→ Also known as 'Biosynthetic Pathway' because ultimately it synthesizes Glucose.

→ Discovered by Melvin Calvin. Hence, also known to be Calvin cycle

→ In dark rxn, 1st stable compound intermediate formed is a 3-carbon compound called Phosphoglycerate (PGA). Hence, called C₃ cycle.

✗ we start calvin cycle with 3 molecules of CO₂ for our convenience. However, naturally, plants execute Calvin cycle with 1 CO₂ molecule.

✓ 6 calvin cycles are needed to synthesize 1 molecule of Glucose.

→ Calvin cycle occurs in 3 steps :-

(i) Carboxylation

(ii) Regeneration Reduction

(iii) Regeneration of RuBP (5c)

→ RuBP = Ribulose Bis-phosphate (5c)

→ RuBP combines with CO₂ in presence of an enzyme called as RuBISCO.

RuBISCO = Ribulose Bisphosphate carboxylase
oxygenase

→ RuBisCo can act as carboxylase as well as oxygenase. under different conditions

For synthesis of 1 molecule of Glucose

$$\left. \begin{array}{l}
 \frac{6 \text{ ATP} + 3 \text{ ATP}}{9 \text{ ATP}} \times 2 = 18 \text{ ATP} \\
 \uparrow \\
 \text{from one Calvin cycle}
 \end{array} \right\} \text{ }$$

$$\left. \begin{array}{l}
 12 \text{ NADPH}_2 \\
 \underline{\hspace{1cm}}
 \end{array} \right\} \text{ }$$

Note:-

→ The 6 molecules of PGA formed in the cycle of rxn is actually fragmented in (5+1) molecule in which 5 molecule is used up in regeneration of RuBP while 1 molecule goes for glucose synthesis.

41 Photorespiration / C_2 cycle / Glycolate cycle takes in

→ Rubisco acts as both carboxylase as well as oxygenase under diff. conditions.

gms Condⁿ for acting as oxygenase :-

* High temp

* High concentration of O_2

↓
Rubisco acts as oxygenase

→ photorespiration is a harmful process in which O_2 is taken in & CO_2 is given out.

→ photorespiration is also called C_2 -cycle because, the first stable compound formed is of 2 carbon containing glycolate.

→ Peroxisome also takes part in this process other than chloroplast & mitochondria.

→ At the time of conversion of glycine (2 moles) into serine (1 mole), the CO_2 is released.

→ Shown by plants of Temperate region

Ex:- wheat, rice, beans, barley.

C₄ Cycle / pathway :-

- Also known as "Hatch-Slack cycle".
- This pathway is used to avoid the problem of photorespiration.
- Photorespiration can be avoided by checking high temp & high $[\text{O}_2]$ concⁿ.

→ Some adaptations are seen in C_4 plants in order to avoid photorespiration.

(1) Dimorphic Chloroplast:-

→ In granal, predominantly, grana is found where light rxn takes place. These are found on upper side of mesophyll cells.

→ However, agranal chloroplast is found in BUNDLE SHEATH cells & predominantly, agranal is full of stroma where dark rxn takes place & there is no release of O_2 .

→ Bundle sheath cells are present in deeper side of leaf, so that the agranal chloroplast might not face the problem of high temp.

(2) Kranz Anatomy:-

→ presence of bundle sheath cells around vascular tissues.

→ It encloses Agranal chloroplast and provides a barrier to O_2 concn in mesophyll cells and also keeps the agranal chloroplast cooler.

→ Hence, to the problem of high $[O_2]$ and high temp. gets solved by some adaptation (like C₄ plants).

→ Ex:- Maize, Sorghum, Sugarcane, Euphorbia, Chenopodium etc.

Pathway:-

PEP = Phosphoenol pyruvate (3C)
 (OAA) = Oxalo Acetic Acid (4C)
 PEPCase = PEP carboxylase.

C₃
 $ATP/Glu \rightarrow 18 \text{ ATP expd}$

C₄
 $ATP/Glu \rightarrow 12 + 18 = 30 \text{ ATP}$

#1 Comparison b/w C_3 & C_4 plants :-

<u>Characters</u>	<u>C_3 plants</u>	<u>C_4 plants</u>
(i) CO_2 acceptor	CO_2 acceptor $\rightarrow$ RuBP	CO_2 acceptor is PEP $\rightarrow$ Mesophyll cells " " " " RuBP $\rightarrow$ Bundle sheath cells
(ii) 1 st stable compound	PGA (phosphoglycerate) (3C)	OAA (oxaloacetic Acid) (4C)
(iii) Types of chloroplast	Granal chloroplast in mesophyll cells.	granal $\rightarrow$ In mesophyll cells Agranal $\rightarrow$ " Bundle sheath cells
(iv) cycle(s)	Only C_3 cycle	C_4 & C_3 cycles.
(v) Site of C_3 cycle	$C_3 \rightarrow$ mesophyll	$C_3 \rightarrow$ In bundle sheath cells
(vi) optimum temp.	10-20°C	30°C
(vii) No. of ATP reqd per glucose formation	18 ATPs	30 ATPs $\begin{cases} 18 \rightarrow C_3 \\ 12 \rightarrow C_4 \end{cases}$
(viii) Enzymes	Rubisco	PEPCO & Rubisco.

#1 CAM Plants / Crassulacean Acid Metabolism :-

$\rightarrow$ This pathway is adopted by the plants of xeric condn, where water loss (transpiration) is a major issue.

$\rightarrow$ They simply change the timing of opening & closing of stomata for gaseous exchange in order to avoid transpiration

$\rightarrow$ Stomata open during night in these plants.

$\rightarrow$ Stomata remains closed during day.

→ Such plants whose stomata opens at night & closes at day are called SCOTOACTIVE Stomata.

→ Ex:- Succulent xerophyte → cacti.
 & Some members of Euphorbeacea family.

pathway:-

During night

During Day

#1 Factors affecting the rate of photosynthesis:-

* Cardinal Points:-

→ By Sachs

→ Any quantity has 3 limits.

let temp:-

↑ Blackmann's Law of Limiting factor :-

↳ Factor which is in least or minimum can decide the rate of photosynthesis

Ex: rate of PS rxn :-

let

Light	Chloro.	CO ₂	H ₂ O
10	10	10	2

So, H₂O is limiting factor as present in min quantity

Factors affecting P.S. rate

External Factors
Light, [CO₂], [O₂], temp, [H₂O]

Internal Factors
Chloro, protoplasm, No. of chloroplasts, No. of stomata & position, Assimilator Number

→ External factors :-

(1) Light :-

(a) quality → Blue to Red

(b) Intensity → Sciophytes ↔ shade plants
Heliophytes ↔ sun plants

(c) Duration → 10-12 hrs.

→ Increase in light int. ↑ rate of P.S

→ Very high light int. slows P.S. & stops.

(2) CO₂ :-

→ slight inc. in CO₂ concn, rate of PS ↑
Called as CO₂ fertilisation effect.

→ Excess CO₂ can reduce P.S. rate.
Called CO₂ toxicity.

(3) O_2 :-

→ Inc. in $[O_2]$ decreases P.S. rate
Called as Warberg's Effect.

→ Inc. in O_2 can increase photorespiration.

(4) Temperature :-

→ Slight increase in temperature increases the rate of P.S.

→ V. High temperature, decrease P.S. ↓
↳ ultimately stops.

(5) H_2O :-

→ Essential for P.S.

→ Internal Factors :-

(1) Protoplasmic factor :-

(2) Chlorophyll Content :-

* Assimilation No. → Amount of CO_2 fixed per gm. of chlorophyll per hour

(3) No. of chloroplasts

(4) No. of stomata & position :-

(5) Accumulation of photosynthate ↓ rate of P.S.

41 Translocation of Photosynthate :-

↓
product of P.S

* Tissue helping in translocation = phloem.

* Translocated from
Site of production → Storage organ
in leaves

Note:-

Rubisco is the most abundant protein in the living world.
